1. Network Summary

- Network Source
- Network Layout
- Network Characteristics

2. Structural Analysis

- Centrality measures
- Page Rank
- Assortative Mixing
- Node structural equivalence
- Closest random graph

3. Community Detection

- Clique search
- Community detection algorithms

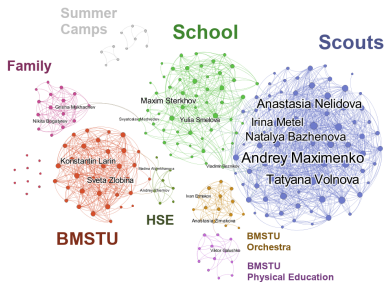

The network is a graph of my friends and our mutual friends in VK social network.

Properties

- Order: 244 nodes
- Size: 1657 edges

Node attributes

- id
- first name
- last name
- city
- university name
- faculty name

Scouts are members of The Scout movements.

Family, School and Scouts are mostly located in Udmurt republic. Other friends are mostly in Moscow.

- Number of connected components: 14
- Diameters of connected components: 7, 5, 6, 3, 2, 0...
- Mean Clustering Coefficient: 0.5712

1. Degree Centrality
2. Closeness Centrality
3. Betweenness Centrality

Top nodes

1. Andrey Maximenko:
Formal and informal leader
of Udmurtian Scouts
(55 mutual friends)
2. Tatyana Volnova:
Formal leader of Udmurtian
Scouts
(49 mutual friends)
3. Anastasia Nelidova:
An experienced scout
(47 mutual friends)

Top nodes

1. Natalya Bazhenova:
Formal leader of Udmurtian
Scouts who now works in
my school
(avg. 2.18 handshakes)
2. Irina "Metel":
A scout leader who lives
close to my school
(avg. 2.23 handshakes)
3. Anastasia Nelidova:
An experienced scout
(avg. 2.3 handshakes)

Top nodes

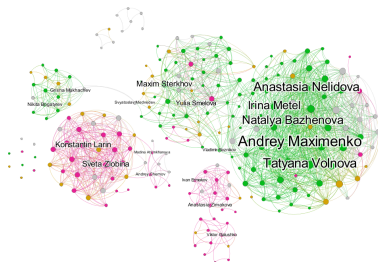

1. Svyatoslav Medvedev:
Played in a school orchestra, knows some of my family
(8% smallest paths)
2. Vladimir Reznikov:
Played in a school orchestra, has a blog
(4.8% smallest paths)
3. Grisha Mukhachev:
Family, knows Svyatoslav Medvedev
(4.5% smallest paths)

Page Rank correlation with Centrality metrics

Top nodes

1. Maxim Sterkhov:
Played in a school orchestra, knows some of my family
(1.13% smallest paths)
2. Andrey Maximenko:
Formal and informal Scout Leader
(1.03% smallest paths)
3. Viktor Galushko:
BMSTU PE teacher
(1.01% smallest paths)

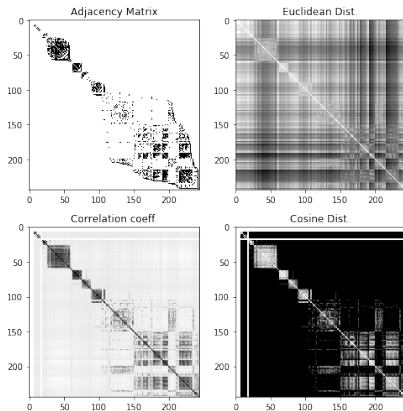

Assortativity Coefficients

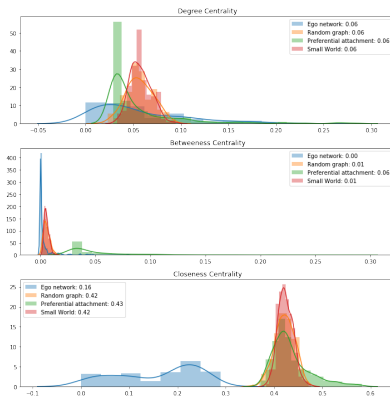

1. City: 0.21
2. University: 0.1
3. Faculty: 0.07

Colors

- Green: Izhevsk
- Red: Moscow
- Orange: Saint-Petersburg
- Grey: Others

Node structural equivalence

Comparing random graph models and Ego network centralities, we obtain ranks of the differences.

Mean difference rank

1. Ego: 1
2. Pref. attachment: 2.67
3. Random graph: 3
4. Small World: 3.33

Therefore the closest random graph model in my case is Preferential attachment.

1. Clique Search
2. Community detection algorithms
 - k-clique communities
 - Modularity based communities
 - Girvan-Newman

People are actively communicate in groups of 5 and 10 persons.

This is totally coherent with the basic theory of amount of people in small in medium size teams.

Coefficient $k = 3$

Results are not well suited for the graph:

- Scouts and School communities are not splitted
- There are unclassified grey points in almost every community.

The results perfectly lie on the network.

The results perfectly lie on the network.
And they look much the same as
Modularity based communities.

These results were taken as
ground truth and were shown in
the very first network layout.
